Abstract

The goal of the LEDA project was to build an easy-to-use and extendable library of correct and efficient data structures, graph algorithms and geometric algorithms. We report on the use of formal program verification to achieve an even higher level of trustworthiness. Specifically, we report on an ongoing and largely finished verification of the blossom-shrinking algorithm for maximum cardinality matching.

2012 ACM Subject Classification Design and Analysis of Algorithms; Software Verification and Validation

Keywords and phrases Graph Algorithms, Correctness, Formal Methods, Software Libraries

Introduction

This talk is a follow-up on two previous invited MFCS-talks given by the second author:

- LEDA: A Library of Efficient Data Types and Algorithms in MFCS 1989 [32], and
- From Algorithms to Working Programs: On the Use of Program Checking in LEDA in MFCS 1998 [34].

After a review of these papers, we discuss the further steps taken to reach even higher trustworthiness of our implementations.

- Formal correctness proofs of checker programs [5, 40], and
- Formal verification of complex graph algorithms [1].

The second item is the technical core of the paper: it reports on the ongoing and largely finished verification of the blossom-shrinking algorithm for maximum cardinality matching in Isabelle/HOL by the first author.

Personal Note by the Second Author: As this paper spans 30 years of work, the reader might get the impression that I followed a plan. This is not the case. As a science, in this case computer science, progresses, there are logical next steps. I took these steps. I did not know 30 years ago, where the journey would lead me.

2 Level One of Trustworthiness: The LEDA Library of Efficient Data Types and Algorithms

In 1989, Stefan Näher and the second author set out to build an easy-to-use and extendable library of correct and efficient data structures, graph algorithms and geometric algorithms. The project was announced in an invited talk at MFCS 1989 [32] and the library is available from Algorithmic Solutions GmbH [28]. LEDA, the library of efficient data types and
template <class NT>
void DIJKSTRA_T(const graph& G, node s, const edge_array<NT>& cost, node_array<NT>& dist, node_array<edge>& pred)
{
  node_pq<NT> PQ(G); // a priority queue for the nodes of G
  node v; edge e;
  dist[s] = 0; // distance from s to s is zero
  PQ.insert(s,0); // insert s with value 0 into PQ
  forall_nodes(v,G) pred[v] = nil; // no incoming tree edge yet
  while (!PQ.empty()) // as long as PQ is non-empty
  {
    node u = PQ.del_min(); // let u be the node with minimum dist in PQ
    NT du = dist[u]; // and du its distance
    forall_adj_edges(e,u) // iterate over all edges e out of u
    {
      v = G.opposite(u,e); // makes it work for ugraphs
      NT c = du + cost[e]; // distance to v via u
      if (pred[v] == nil && v != s) // v already reached?
        PQ.insert(v,c); // first path to v
      else if (c < dist[v]) PQ.decrease_p(v,c); // better path
        else continue;
      dist[v] = c; // store distance value
      pred[v] = e; // and incoming tree edge
    }
  }
}

Figure 1 The LEDA implementation of Dijkstra’s algorithm: Note that the executable code above is similar to a typical pseudo-code presentation of the algorithm.

algorithms, offers a flexible data type graph with loops for iterating over edges and nodes and arrays indexed by nodes and edges. It also offers the data types required for graph algorithms such as queues, stacks, and priority queues. It thus created a framework in which graph algorithms can be formulated easily and naturally, see Figure 1 for an example. The design goal was to create a system in which the difference between the pseudo-code used to explain an algorithm and what constitutes an executable program is as small as possible. The expectation was that this would ease the burden of the implementer and make it easier to get implementations correct.

3 Level Two of Trustworthiness: Certifying Algorithms

Nevertheless, some implementations in the initial releases were incorrect, in particular, the planarity test\textsuperscript{1}; it declared some planar graphs non-planar. At around 1995, we adopted the concept of certifying algorithms [34, 31] for the library and reimplemented all algorithms [35].

A certifying algorithm computes for each input a easy-to-check certificate (witness) that demonstrates to the user that the output of the program for this particular input is correct; see Figure 2. For example, the certifying planarity test returns a Kuratowski subgraph if it

\textsuperscript{1} Most of the implementations of the geometric algorithms were also incorrect in their first release as we had naïvely used floating point arithmetic to implement real arithmetic and the rounding errors invalidated the implementations of the geometric primitives. This lead to the development of the exact computation paradigm for geometric computing by us and others [21, 46, 14, 45, 33]. In this paper, we restrict to graph algorithms.
Certifying program for IO-behavior \((\varphi, \psi)\)

Checker \(C\)

\[ x \quad \text{accept} \quad y \]
\[ w \quad \text{reject} \]

Figure 2 The top figure shows the I/O behavior of a conventional program for IO-behavior \((\varphi, \psi)\); here \(\varphi\) is the precondition and \(\psi\) is the postcondition. The user feeds an input \(x\) satisfying \(\varphi(x)\) to the program and the program returns an output \(y\) satisfying \(\psi(x, y)\). A certifying algorithm for IO-behavior \((\varphi, \psi)\) computes \(y\) and a witness \(w\). The checker \(C\) accepts the triple \((x, y, w)\) if and only if \(w\) is a valid witness for the postcondition \(\psi(x, y)\), i.e., it proves \(\psi(x, y)\). (reprinted from [5])

declares the input graph non-planar and a (combinatorial) planar embedding if it declares the input graph planar, and the maximum cardinality matching algorithm computes a matching and an odd-set-cover that proves its optimality; see Figures 3 and 4. The state of the art of certifying algorithms is described in [31]. We also implemented checker programs that check the witness for correctness and argued that the checker programs are so simple that their correctness is evident. From a pragmatic point of view, the goals of the project were reached by 2010. The library was easy-to-use and extendable, the implementations were efficient, and no error was discovered in any of the graph algorithms for several years despite intensive use by a commercial and academic user community.

Note that, most likely, errors would not have gone undiscovered because of the use of certifying algorithms and checker programs. Only if a module produced an incorrect output and hence an invalid certificate and the checker program missed to uncover the invalidity of the certificate would an error go unnoticed. Of course, the possibility is there and the phrase “most likely” in the preceding sentence has no mathematical meaning.

Alternative libraries such as Boost and LEMON [44, 29] are available now and some of their implementations are slightly more efficient than ours. However, none of the new libraries pays the same attention to correctness. For example, all libraries allow floating point numbers as weights and capacities in network algorithms, but only LEDA ensures that the intricacies of floating point arithmetic do not invalidate the implementations; see [6] and [35, Section 7.2].

4 Level Three of Trustworthiness: Formal Verification of Checkers

We stated above that the checker programs are so simple that their correctness is evident. Shouldn’t they then be amenable to formal verification? Harald Ganzinger and the second author attempted to do so at around 2000 and failed. About 10 years later (2011 – 2014) Eyad Alkassar from the Verisoft Project [43], Sascha Böhme and Lars Noschinski from Tobias Nipkow’s group at TU München, and Christine Rizkallah and the second author succeeded in formally verifying some of the checker programs [5, 40]. In order to be able to talk about formal verification of checker programs, we need to take a more formal look at certifying algorithms.
A matching in a graph $G$ is a subset $M$ of the edges of $G$ such that no two share an endpoint.

An odd-set cover $OSC$ of $G$ is a labeling of the nodes of $G$ with non-negative integers such that every edge of $G$ (which is not a self-loop) is either incident to a node labeled 1 or connects two nodes labeled with the same $i$, $i \geq 2$.

Let $n_i$ be the number of nodes labeled $i$ and consider any matching $N$. For $i, i \geq 2$, let $N_i$ be the edges in $N$ that connect two nodes labeled $i$. Let $N_1$ be the remaining edges in $N$. Then $|N_i| \leq \lfloor n_i/2 \rfloor$ and $|N_1| \leq n_1$ and hence

$$|N| \leq n_1 + \sum_{i \geq 2} \lfloor n_i/2 \rfloor$$

for any matching $N$ and any odd-set cover $OSC$. It can be shown that for a maximum cardinality matching $M$ there is always an odd-set cover $OSC$ with

$$|M| = n_1 + \sum_{i \geq 2} \lfloor n_i/2 \rfloor,$$

thus proving the optimality of $M$. In such a cover all $n_i$ with $i \geq 2$ are odd, hence the name.

```c
list<edge> MAX_CARD_MATCHING(graph G, node_array<int>& OSC)
    computes a maximum cardinality matching $M$ in $G$ and returns it as a list of edges.
    The algorithm ([12], [15]) has running time $O(nm \cdot \alpha(n,m))$.
    An odd-set cover that proves the maximality of $M$ is returned in $OSC$.
```

```c
bool CHECK_MAX_CARD_MATCHING(graph G, list<edge> M, node_array<int> OSC)
    checks whether $M$ is a maximum cardinality matching in $G$ and $OSC$ is a proof of
    optimality. Aborts if this is not the case.
```

Figure 3 The LEDA manual page for maximum cardinality matchings (reprinted from [34]).

We consider algorithms which take an input from a set $X$ and produce an output in a set $Y$ and a witness in a set $W$. The input $x \in X$ is supposed to satisfy a precondition $\varphi(x)$, and the input together with the output $y \in Y$ is supposed to satisfy a postcondition $\psi(x, y)$. A witness predicate for a specification with precondition $\varphi$ and postcondition $\psi$ is a predicate $W \subseteq X \times Y \times W$, where $W$ is a set of witnesses with the following witness property:

$$\varphi(x) \land W(x, y, w) \rightarrow \psi(x, y).$$

The checker program $C$ receives a triple\(^2\) $(x, y, w)$ and is supposed to check whether it fulfills the witness property. If $\neg\varphi(x)$, $C$ may do anything (run forever or halt with an arbitrary output). If $\varphi(x)$, $C$ must halt and either accept or reject. It is required to accept if $W(x, y, w)$ holds and is required to reject otherwise. This results in the following proof obligations.

**Checker Correctness:** We need to prove that $C$ checks the witness predicate assuming that the precondition holds, i.e., on input $(x, y, w)$:

(i) If $\varphi(x)$, $C$ halts.
(ii) If $\varphi(x)$ and $W(x, y, w)$, $C$ accepts $(x, y, w)$, and if $\varphi(x)$ and $\neg W(x, y, w)$, $C$ rejects the triple.

\(^2\) We ignore the minor complication that $X, Y,$ and $W$ are abstract sets and programs handle concrete representations.
Figure 4 The checker for maximum cardinality matchings (reprinted from [34]).

Witness Property: We need to prove implication (1).

In case of the maximum cardinality matching problem, the witness property states that an odd-set cover $OSC$ as defined in Figure 3 with $|M| = n_1 + \sum_{i \geq 2} \lfloor n_i/2 \rfloor$ proves that the matching $M$ has maximum cardinality. Checker correctness amounts to the statement that the program shown in Figure 4 is correct.

We proved the witness property using Isabelle/HOL [38]. For the checker correctness, we used VCC [9] and later Simpl [42] and AutoCorres [16]. The latter approach has the advantage that the entire verification can be performed within Isabelle. Simpl is a generic imperative programming language embedded into Isabelle/HOL, which was designed as an intermediate language for program verification. We implemented checkers both in Simpl and C. Checkers written in Simpl were verified directly within Isabelle. For the checkers written in C, we first translated from C to Isabelle using the C-to-Isabelle parser that was developed as part of the sel4 project [22], and then used the AutoCorres tool developed at NICTA that simplifies reasoning about C in Isabelle/HOL. Christine spent several months at NICTA to learn how to use the tool. We verified the checkers for connectivity, maximum cardinality matching, and non-planarity. In particular, for the non-planarity checker it was essential that Lars Noschinski in parallel formalized basic graph theory in Isabelle [39].
A disclaimer is in order here. We did not verify the C++ program shown in Figure 4. Rather we verified a manual translation of this program into Simple or C, respectively. For this translation, we assumed a very basic representation of graphs. The nodes are numbered from 0 to \(n-1\), the edges are numbered from 0 to \(m-1\) with the edges incident to any vertex numbered consecutively and arrays of the appropriate dimension are used for cross-referencing and for encoding adjacency lists.

The verification attempt for the maximum cardinality checker shown in Figure 4 discovered a flaw. Note that the program does not check whether the edges in \(M\) actually belong to \(G\). When we wrote the checker, we apparently took this for granted. The verification attempt revealed the flaw.

We also considered going further and briefly tried to verify the LEDA maximum cardinality matching algorithm [35, Section 7.7]. The program has 330 lines of code and the description of the algorithm, its implementation and its correctness proof spans over 20 pages. We found the task too daunting and, extrapolating from the effort required for the verification of the checkers, estimated the effort as several man-years.

5 Level Four of Trustworthiness: Formal Verification of Complex Algorithms

A decade later, we perform the formal verification of the blossom-shrinking algorithm for maximum cardinality. We give a short account of the verification which will be described in detail in our forthcoming publication [1]. On a high-level Edmond’s blossom-shrinking algorithm [12] works as follows. The algorithm repeatedly searches for an augmenting path with respect to the current matching. Initially, the current matching is empty. Whenever an augmenting path is found, augmentation of the path increases the size of the matching by one. If no augmenting path exists with respect to the current matching, the current matching has maximum cardinality.

The search for an augmenting path is via growing alternating trees rooted at free vertices, i.e. vertices not incident to an edge of the matching. The search is initialised by making each free vertex a root of an alternating tree; the matched nodes are in no tree initially. In an alternating tree, vertices at even depth are entered by a matching edge, vertices at odd depth are entered by a non-matching edge, and all leaves have even depth. In each step of the growth process, one considers a vertex, say \(u_1\), of even depth that is incident to an edge \(\{u_1, u_2\}\) not considered before. If \(u_2\) is not in a tree yet, then one adds \(u_2\) (at odd level) and its mate (at even level) under the current matching to the tree. If \(u_2\) is already in a tree and has odd level then one does nothing as one simply has discovered another odd length path to \(u_2\). If \(u_2\) is already in a tree and has even level then one has either discovered an augmenting path (if \(u_2\) is in a different tree than \(u_1\)) or a blossom (if \(u_2\) and \(u_1\) are in the same tree). In the latter case, consider the tree paths from \(u_2\) and \(u_1\) back to their common root and let \(u_3\) be the lowest common ancestor of \(u_2\) and \(u_1\). The edge \(\{u_1, u_2\}\) plus the tree paths from \(u_1\) and \(u_2\) to \(u_3\) form an odd length cycle. One collapses all nodes on the cycle into a single node and repeats the search for an augmenting path in the quotient (= shrunken) graph. If an augmenting path is found in the quotient graph, it is lifted (refined) to an augmenting path in the original graph. If no augmenting path exists in the quotient graph, no augmenting path exists in the original graph. In this section, we describe in detail the algorithm outlined above, and the process of formalising and verifying it in Isabelle/HOL.
5.1 Isabelle/HOL

Isabelle/HOL [41] is a theorem prover for classical Higher-Order Logic. Roughly speaking, Higher-Order Logic can be seen as a combination of functional programming with logic. Isabelle’s syntax is a variation of Standard ML combined with (almost) standard mathematical notation. Application of function \( f \) to arguments \( x_1 \ldots x_n \) is written as \( f(x_1 \ldots x_n) \). We explain non-standard syntax in the paper where it occurs.

Isabelle is designed for trustworthiness: following the LCF approach [36], a small kernel implements the inference rules of the logic, and, using encapsulation features of ML, it guarantees that all theorems are actually proved by this small kernel. Around the kernel, there is a large set of tools that implement proof tactics and high-level concepts like algebraic data types and recursive functions. Bugs in these tools cannot lead to inconsistent theorems being proved since they all rely on the kernel only, but only to error messages when the kernel refuses a proof. Isabelle/HOL comes with a rich set of already formalized theories, among which are natural numbers and integers as well as sets and finite sets.

5.2 Preliminaries

An edge is a set of vertices with size 2. A graph \( G \) is a set of edges. A set of edges \( M \) is a matching iff \( \forall e, e' \in M. e \cap e' = \emptyset \). In Isabelle/HOL that is represented as follows:

\[
\text{matching } M \iff (\forall e_1 \in M. \forall e_2 \in M. e_1 \neq e_2 \rightarrow e_1 \cap e_2 = \{\})
\]

In may cases, a matching is a subset of a graph, in which case we call it a matching w.r.t. the graph. For a graph \( G, M \) is a maximum matching w.r.t. \( G \) iff for any matching \( M' \) w.r.t. \( G \), we have that \( |M'| \leq |M| \).

5.3 Formalising Berge’s Lemma

A list of vertices \( u_1u_2\ldots u_n \) is a path w.r.t. a graph \( G \) iff every \( \{u_i, u_{i+1}\} \in G \). A path \( u_1u_2\ldots u_n \) is a simple path iff for every \( 1 \leq i \neq j \leq n \), \( u_i \neq u_j \). A list of vertices \( u_1u_2\ldots u_n \) is an alternating path w.r.t. a set of edges \( E \) iff for some \( E' \) (i) \( E' = E \) or \( E' = \{e \mid e \not\in E\} \), (ii) \( \{u_i, u_{i+1}\} \in E' \) holds for all even numbers \( i \), where \( 1 \leq i < n \), and (iii) \( \{u_i, u_{i+1}\} \not\in E' \) holds for all odd numbers \( i \), where \( 1 \leq i \leq n \). We call a list of vertices \( u_1u_2\ldots u_n \) an augmenting path w.r.t. a matching \( M \) iff \( u_1u_2\ldots u_n \) and \( u_1, u_n \not\in \bigcup M \). It is often the case that an augmenting path \( \gamma \) w.r.t. to a matching \( M \) is also a simple path w.r.t. a graph \( G \), in which case we call the path an augmenting path w.r.t. to the pair \( (G, M) \). Also, for two sets \( s \) and \( t \), \( s \oplus t \) denotes the symmetric difference of the two sets. We overload \( \oplus \) to arguments which are lists in the obvious fashion.

\( \triangleright \) Theorem 1 (Berge’s Lemma). For a graph \( G \), a matching \( M \) is maximum w.r.t. \( G \) iff there is not an augmenting path \( \gamma \) w.r.t. \( (G, M) \).

Our proof of Berge’s lemma is shorter than the standard proof. The standard proof consists of three steps. First, for any two matchings \( M \) and \( M' \), every connected component of the graph \( M \oplus M' \) is either (i) a singleton vertex, (ii) a path, or (iii) a cycle. Second, for a set of edges \( C \subseteq M \oplus M' \) s.t. \( |C \cap M| < |C \cap M'| \), the edges from \( C \) form a path. Thirds, such a set \( C \) of edges exists, if \( |M| < |M'| \). We observe that it is much easier to directly show that such a \( C \) exists and that all its edges can be arranged in a path, without having to prove the first step about all connected components. We found this different proof during the process of formalising the theorem, and finding this shorter proof was primarily motivated...
by making the formalisation shorter and more feasible. The discovery of simpler proofs or
more general theorem statements is one potential positive outcome of verifying algorithms,
and mathematics in general, in interactive theorem provers [3, 2, 10].

Algorithm 1: FIND_MAX_MATCHING(G, M)

\[
\gamma := \text{AUG_PATH_SEARCH}(G, M)
\]

if \(\gamma\) is some augmenting path

return FIND_MAX_MATCHING(G, M \oplus \gamma)

else

return M

Now consider Algorithm 1. Berge’s lemma implies the validity of that algorithm as a
method to compute maximum matchings in graphs. The validity of Algorithm 1 is stated in
the following corollary.

\[\text{Corollary 1.}\] Assume that \(\text{AUG_PATH_SEARCH}(G, M)\) is an augmenting path w.r.t.
\((G, M)\), for any graph \(G\) and matching \(M\), iff \(G\) has an augmenting path w.r.t. \((G, M)\). Then,
for any graph \(G\), FIND_MAX_MATCHING(G, \emptyset) is a maximum matching w.r.t. \(G\).

As shown in Corollary 1, Algorithm 1 depends on the function \(\text{AUG_PATH_SEARCH}\) which
is a sound and a complete procedure to compute augmenting paths in graphs.

In Isabelle/HOL, the first step is to formalise the path concepts from above. Paths and
alternating paths are defined recursively in a straightforward fashion. An augmenting path
is defined as follows:

\[
\text{augmenting_path } M p \equiv (\text{length } p \geq 2) \land \text{alt_path } M p \\
\land \text{hd } p \notin \text{Vs } M \land \text{last } p \notin \text{Vs } M
\]

The formalised statement of Berge’s lemma is as follows:

\[\text{theorem Berge:}\]

assumes

finite \(M\) and matching \(M\) and \(M \subseteq E\)
and

\((\forall e \in E. \exists u v. e = \{u, v\} \land u \neq v)\) and finite (Vs E)

shows \((\exists p. \text{augmenting_path } M p \land \text{path } E p \land \text{distinct } p) \iff \exists M' \subseteq E. \text{matching } M' \land \text{card } M < \text{card } M')\)

Note that in the formalisation when the paths need to be simple, such as in Berge’s lemma
above, we have the additional assumption that all vertices are pairwise distinct, denoted by
the Isabelle/HOL predicate distinct. Just to clarify Isabelle’s syntax: the lemma above has
two sets of assumptions, one on the matching and the other on the graph. The matching has
to be a finite set, which is a matching w.r.t. the given graph. The graph has to have edges
which only have two vertices, and its set of vertices has to be finite.

In Isabelle/HOL Algorithm 1 is formalised within the following locale.

locale find_max_match =

fixes aug_path_search::'a set set => 'a set set => ('a list) option and

E assumes

aug_path_search_complete:
matching M \land M \subseteq E \land finite M \land

(\exists p. \text{path } E p \land \text{distinct } p \land \text{augmenting_path } M p)
and
\[
\text{aug_path_search\_sound:}
\]
\[
\text{matching } M \land M \subseteq E \land \text{finite } M \land \text{aug_path_search } E M = \text{Some } p \implies
\]
\[
\text{path } E p \land \text{distinct } p \land \text{augmenting\_path } M p
\]
\]

and
\[
\text{graph: } \forall e \in E. \exists u v. e = \{u, v\} \land u \neq v \land \text{finite } (Vs E)
\]

A locale is a named context: definitions and theorems proved within locale \texttt{find\_max\_match}
can refer to the parameters and assumptions declared there. In this case, we need the
locale to identify the parameter \texttt{aug\_path\_search} of the locale, corresponding to the function
\texttt{Aug\_Path\_Search}, which is used in Algorithm 1. The function \texttt{aug\_path\_search} should
take as input a graph and a matching. It should return an \texttt{('a list) option} typed value.
Generally speaking, the value of an \texttt{('a option} valued term could be in one of two forms:
either \texttt{Some } x, \text{ or } \texttt{None}, where \texttt{x} is of type \texttt{'a}. In the case of \texttt{aug\_path\_search}, it should return
either \texttt{Some } p, where \texttt{p} is a path in case an augmenting path is found, or \texttt{None}, otherwise.
There is also the function \texttt{the}, which given a term of type \texttt{('a option}, returns \texttt{x}, if the given
term is \texttt{Some } x, and which is undefined otherwise. Within that locale, the definition of
Algorithm 1 and its verification theorem are as follows. Note that the correctness theorem
has four conclusions: the algorithm returns a subset of the graph, that subset is a matching,
that matching is finite and the cardinality of any other matching is bounded by the size of
the returned matching.

\[
\text{find\_max\_matching } M =
\]
\[
\text{(if } \exists p. \text{aug\_path\_search } E M = \text{Some } p \text{ then}
\]
\[
\text{(find\_max\_matching } (M \oplus (\text{set } (\text{edges\_of\_path } (\text{the } (\text{aug\_path\_search } E M)))))))
\]
\[
\text{else } M)
\]

\[
\text{lemma find\_max\_matching\_works:}
\]
\[
\text{shows } (\text{find\_max\_matching } \{\}) \subseteq E
\]
\[
\text{matching } (\text{find\_max\_matching } \{\})
\]
\[
\text{finite } (\text{find\_max\_matching } \{\})
\]
\[
\forall M. \text{matching } M \land M \subseteq E \land \text{finite } M \implies \text{card } M \leq \text{card } (\text{find\_max\_matching } \{\})
\]

Functions defined within a locale are parameterised on the constants which are declared
in the locale’s definition. When a function is used outside a locale, these parameters must be
specified. So, if \texttt{find\_max\_matching} is used outside the locale above, it should take as a parameter
a function which computes augmenting paths. Similarly, theorems proven within a locale
implicitly have the assumptions of the locale. So if we use the lemma \texttt{find\_max\_matching\_works},
we would have to prove that the functional argument to \texttt{find\_max\_matching} satisfies the
assumptions of the locale, i.e. that argument is a sound and complete procedure for computing
augmenting paths. The way theorems from locales are used will be clearer in the next section
when we refer to the function \texttt{find\_max\_matching} and use the lemma \texttt{find\_max\_matching\_works}
outside of the locale \texttt{find\_max\_match}. The use of locales for performing gradual refinement of
algorithms allows to focus on the specific aspects of the algorithm relevant to a refinement
stage, with the rest of the algorithm abstracted away.

### 5.4 Verifying that Blossom Contraction Works

In Corollary 1, which specifies the soundness of \texttt{Find\_Max\_Matching}, we have not
explicitly specified the function \texttt{Aug\_Path\_Search}. Indeed, we have only specified what its
output has to conform to. We now refine that specification and describe \texttt{Aug\_Path\_Search} algorithmically.

Firstly, for a function \( f \) and a set \( s \), let \( f[s] \) denote the image of \( f \) on \( s \). Also, for a set of edges \( E \), and a function \( f \), the quotient \( E/f \) is the set \( \{ f[e] \mid e \in E \} \). We now introduce the concepts of a \textit{blossom}. A list of vertices \( u_1 u_2 \ldots u_n \) is called a cycle if \( 3 < n \) and \( u_n = u_1 \), and we call it an odd cycle if \( n \) is even. A pair \( \langle u_1 u_2 \ldots u_{i−1}, u_i u_{i+1} \ldots u_n \rangle \) is a blossom w.r.t. a matching \( \mathcal{M} \) iff (i) \( u_1 u_{i+1} \ldots u_n \) is an odd cycle, (ii) \( u_1 u_2 \ldots u_n \) is an alternating path w.r.t. \( \mathcal{M} \), and (iii) \( u_1 \notin \bigcup \mathcal{M} \). We also refer to \( u_1 u_2 \ldots u_{i} \) as the stem of the blossom. In many situations we have a pair \( \langle u_1 u_2 \ldots u_{i−1}, u_i u_{i+1} \ldots u_n \rangle \) which is a blossom w.r.t. a matching \( \mathcal{M} \) where \( u_1 u_2 \ldots u_{i−1} u_i u_{i+1} \ldots u_n−1 \) is also a simple path w.r.t. a graph \( \mathcal{G} \) and \( \{ u_{n−1}, u_n \} \in \mathcal{G} \). In this case we call it a blossom w.r.t. \( \langle \mathcal{G}, \mathcal{M} \rangle \).

Based on the above definitions, we prove that contracting (i.e. shrinking) the odd cycle of a blossom preserves the existence of an augmenting path, which is the second main result needed to prove the validity of the blossom-shrinking algorithm, after Berge’s lemma.

\begin{theorem}
Consider a graph \( \mathcal{G} \) and a vertex \( u \notin \bigcup \mathcal{G} \). Let for a set \( s \), the function \( P_s \) be defined as \( P_s(x) = \{ y \in x \text{ then } u \text{ else } x \} \). Then, for a blossom \( \langle \gamma, \mathcal{C} \rangle \text{ w.r.t. } \langle \mathcal{G}, \mathcal{M} \rangle \), if \( s \) is the set of vertices in \( \mathcal{C} \), then we have an augmenting path w.r.t. \( \langle \mathcal{G}, \mathcal{M} \rangle \) iff there is a blossom w.r.t. \( \langle \mathcal{G}/P_s, \mathcal{M}/P_s \rangle \).
\end{theorem}

Theorem 2 is used in most expositions of the blossom-shrinking algorithm. In our proof for the forward direction (if an augmenting path exists w.r.t. \( \langle \mathcal{G}, \mathcal{M} \rangle \), then there is an augmenting path w.r.t. \( \langle \mathcal{G}/P_s, \mathcal{M}/P_s \rangle \), i.e. w.r.t. the quotients), we follow a standard textbook approach [23]. In our proof for the backward direction (an augmenting path w.r.t. the quotients can be lifted to an augmenting path w.r.t. the original graph we define an (almost) executable function \texttt{refine} that does the lifting.\footnote{The function \texttt{refine}, as defined later, is executable except for a choice operation.} We took the choice of explicitly defining that function with using it in the final algorithm in mind. This is similar to the approach used in the informal proof of soundness of the variant of the blossom-shrinking algorithm used in LEDA [35].

Now, using Theorem 2, one can show that Algorithm 2 is a sound and complete procedure for computing augmenting paths.

\begin{algorithm}[H]
\begin{algorithmic}
\State \textbf{if} \texttt{Compute\_Blossom}(\( \mathcal{G}, \mathcal{M} \)) \textbf{is} a blossom \( \langle \gamma, \mathcal{C} \rangle \text{ w.r.t. } \langle \mathcal{G}, \mathcal{M} \rangle \)
\State \quad \textbf{return} \texttt{refine} (\texttt{Aug\_Path\_Search}(\( \mathcal{G}/P_C, \mathcal{M}/P_C \)))
\State \textbf{else if} \texttt{Compute\_Blossom}(\( \mathcal{G}, \mathcal{M} \)) \textbf{is} an augmenting path w.r.t. \( \langle \mathcal{G}, \mathcal{M} \rangle \)
\State \quad \textbf{return} \texttt{Compute\_Blossom}(\( \mathcal{G}, \mathcal{M} \))
\State \textbf{else}
\State \quad \textbf{return} \texttt{no} augmenting path \texttt{found}
\end{algorithmic}
\end{algorithm}

The soundness and completeness of this algorithm assumes that \texttt{Compute\_Blossom} can successfully compute a blossom or an augmenting path in a graph iff either one exists. This is formally stated as follows.

\begin{corollary}
Assume that, for a graph \( \mathcal{G} \) and a matching \( \mathcal{M} \text{ w.r.t. } \mathcal{G} \), there is a blossom or an augmenting path w.r.t. \( \langle \mathcal{G}, \mathcal{M} \rangle \) iff \texttt{Compute\_Blossom}(\( \mathcal{G}, \mathcal{M} \)) is a blossom or an augmenting
path w.r.t. \( (G, M) \). Then for any graph \( G \) and matching \( M \), \( \text{AUG\_PATH\_SEARCH}(G, M) \) is an augmenting path w.r.t. \( (G, M) \) iff there is an augmenting path w.r.t. \( (G, M) \).

To formalise that in Isabelle/HOL, an odd cycle and a blossom are defined as follows:

\[
\text{odd_cycle } p \equiv (\text{length } p \geq 3) \land \text{odd (length (edges_of_path } p)) \land \text{hd } p = \text{last } p
\]

\[
\text{blossom } M \text{ stem } C \equiv \text{alt_path } M (\text{stem } @ C) \land \\
\text{distinct (stem } @ (\text{butlast } C)) \land \text{odd_cycle } C \land \text{hd (stem } @ C) \notin \text{Vs } M \land \\
\text{even (length (edges_of_path (stem } @ [\text{hd } C]))}
\]

In the above definition \( @ \) stands for list concatenation and \( \text{edges_of_path} \) is a function which, given a path, returns the list of edges constituting the path.

To define the function \( \text{refine} \) that refines a quotient augmenting path to a concrete one or to formalise the theorems showing that contracting blossoms preserves augmenting paths we first declare the following locale:

\[
\text{locale quot =} \\
\text{fixes } P \ s \ u \\
\text{assumes } \forall v \in \ s. P v = v \land u \notin \ s \land (\forall v. v \notin \ s \rightarrow P v = u)
\]

That locale fixes a function \( P \), a set of vertices \( s \) and a vertex \( u \). The function \( P \) maps all vertices from \( s \) to the given vertex \( u \).

Now, we formalise the function \( \text{refine} \) which lifts an augmenting path in a quotient graph to an augmenting path in the concrete graph. The function \( \text{refine} \) takes an augmenting path \( p \) in the quotient graph and returns it unchanged if it does not contain the vertex \( u \) and deletes \( u \) and splits \( p \) into two paths \( p_1 \) and \( p_2 \) otherwise. In the latter case, \( p_1 \) and \( p_2 \) are passed to \( \text{replace_cycle} \). This function first defines two auxiliary paths \( \text{stem2p2} \) and \( \text{p12stem} \) using the function \( \text{stem2vert_path} \). Let us have a closer look at the path \( \text{stem2p2} \). \( \text{stem2vert_path} \) with last argument \( \text{hd } p2 \) uses \( \text{choose_con_vert} \) to find a neighbor of \( \text{hd } p2 \) on the cycle \( C \). It splits the cycle at this neighbor and then returns the path leading to the base of the blossom starting with a matching edge. Finally, \( \text{replace_cycle} \) glues together \( p_1 \), \( p_2 \) and either \( \text{stem2p2} \) and \( \text{p12stem} \) to obtain an augmenting path in the concrete graph.

\[
\text{choose_con_vert } vs \ E \ v \equiv (\text{SOME } v'. v' \in vs \land \{v, v'\} \in E)
\]

\[
\text{stem2vert_path } C \ E \ M \ v \equiv \\
\text{let } \text{find_pfx'} = (\forall C. \text{find_pfx'} ((=) (\text{choose_con_vert (set } C) E v)) C) \text{ in} \\
\text{if } (\text{last (edges_of_path } (\text{find_pfx'} C)) \in M) \text{ then} \\
(\text{find_pfx'} C) \\
\text{else} \\
(\text{find_pfx'} (\text{rev } C))
\]

\[
\text{replace_cycle } C \ E \ M \ p1 \ p2 \equiv \\
\text{let } \text{stem2p2} = \text{stem2vert_path } C \ E \ M \ (\text{hd } p2); \\
\text{p12stem} = \text{stem2vert_path } C \ E \ M \ (\text{last } p1) \text{ in} \\
\text{if } p1 = [] \text{ then} \\
\text{stem2p2 } \ominus p2 \\
\text{else} \\
(\text{if } p2 = [] \text{ then} \\
\text{p12stem } \ominus (\text{rev } p1) \\
\text{else} \\
(\text{if } \{u, \text{hd } p2\} \notin \text{quotG } M \text{ then})
\]

\[
\text{if } \text{odd_cycle } (\text{last } (\text{edges_of_path } (\text{stem } @ [\text{hd } C])))
\]

\[
\text{blossom } M \text{ stem } C \equiv \text{alt_path } M (\text{stem } @ C) \land \\
\text{distinct (stem } @ (\text{butlast } C)) \land \text{odd_cycle } C \land \text{hd (stem } @ C) \notin \text{Vs } M \land \\
\text{even (length (edges_of_path (stem } @ [\text{hd } C]))}
\]

\[
\text{choose_con_vert } vs \ E \ v \equiv (\text{SOME } v'. v' \in vs \land \{v, v'\} \in E)
\]

\[
\text{stem2vert_path } C \ E \ M \ v \equiv \\
\text{let } \text{find_pfx'} = (\forall C. \text{find_pfx'} ((=) (\text{choose_con_vert (set } C) E v)) C) \text{ in} \\
\text{if } (\text{last (edges_of_path } (\text{find_pfx'} C)) \in M) \text{ then} \\
(\text{find_pfx'} C) \\
\text{else} \\
(\text{find_pfx'} (\text{rev } C))
\]

\[
\text{replace_cycle } C \ E \ M \ p1 \ p2 \equiv \\
\text{let } \text{stem2p2} = \text{stem2vert_path } C \ E \ M \ (\text{hd } p2); \\
\text{p12stem} = \text{stem2vert_path } C \ E \ M \ (\text{last } p1) \text{ in} \\
\text{if } p1 = [] \text{ then} \\
\text{stem2p2 } \ominus p2 \\
\text{else} \\
(\text{if } p2 = [] \text{ then} \\
\text{p12stem } \ominus (\text{rev } p1) \\
\text{else} \\
(\text{if } \{u, \text{hd } p2\} \notin \text{quotG } M \text{ then})
\]

\[
\text{odd_cycle } p \equiv (\text{length } p \geq 3) \land \text{odd (length (edges_of_path } p)) \land \text{hd } p = \text{last } p
\]
p1 @ stem2p2 @ p2
else
(rev p2) @ p12stem @ (rev p1))

refine C E M p ≡
if (u ∈ set p) then
(replace_cycle C E M (fst (pref_suf [] u p)) (snd (pref_suf [] u p)))
else p

In Isabelle/HOL the two directions of the equivalence in Theorem 2 are formalised as follows:

**Theorem quot_apath_to_aPath:**

assumes
odd_cycle C and alt_path M C and distinct (tl C) and path E C and augmenting_path (quotG M) p' and distinct p' and path (quotG E) p' and matching M and M ⊆ E and s = (Vs E) - set C and ∀ e ∈ E. ∃ u v. e = {u, v} ∧ u ≠ v

shows augmenting_path M (refine C E M p') ∧ path E (refine C E M p') ∧ distinct (refine C E M p')

**Theorem aug_path_works_in_contraction:**

assumes
path E (stem @ C) and blossom M stem C and augmenting_path M p and path E p and distinct p and matching M and M ⊆ E and finite M and s = (Vs E) - set C and u ∉ Vs E and ∀ e ∈ E. ∃ u v. e = {u, v} ∧ u ≠ v and finite (Vs E)

shows ∃ p'. augmenting_path (quotG M) p' ∧ path (quotG E) p' ∧ distinct p'

A main challenge with formalising Theorem 2 in Isabelle/HOL is the lack of automation for handling symmetries in its proof.

To formalise Algorithm 2 we use a locale to assume the existence of the function which computes augmenting paths or blossoms, if either one exist. That function is called blos_search in the locale declaration. Its return type and the assumptions on it are as follows:

datatype 'a blossom_res =
Path (aug_path: '"a list") | Blossom (stem_vs: '"a list") (cycle_vs: '"a list")

bloss_algo_complete:
((∃ p. path E p ∧ distinct p ∧ augmenting_path M p)
∨ (matching M ∧ (∃ stem C. path E (stem @ C) ∧ blossom M stem C)))
⇒ (∃ blos_comp. blos_search E M = Some blos_comp)

bloss_algo_sound:
\[(\forall e \in E. \exists u, v. e = \{u, v\} \land u \neq v) \land \text{blos_search} E M = \text{Some} (\text{Path} p) \]
\[\implies (\text{path} E p \land \text{distinct} p \land \text{augmenting_path} M p)\]
\[\text{blos_search} E M = \text{Some} (\text{Blossom} \text{stem} C) \]
\[\implies (\text{path} E (\text{stem} \circ C) \land (\text{matching} M \rightarrow \text{blossom} M \text{stem} C))\]

The locale also fixes a function \text{create_vert} which creates new vertex names to which vertices from the odd cycle are mapped during contraction. Within that locale, we define Algorithm 2 and prove its soundness and completeness theorems, which are as follows:

\[
\text{quotG} E \equiv (\text{quot_graph} P E) - \{(u)\}
\]

\[
\begin{align*}
\text{find_aug_path} E M &= \quad \text{(case blos_search} E M \text{ of Some} \text{blossom_res} \Rightarrow \text{case} \text{blossom_res} \text{ of Path} p \Rightarrow \text{Some} p \\
& \quad | \text{Blossom} \text{stem} \text{cyc} \Rightarrow \text{let} u = \text{create_vert} (\text{Vs} E); \\
& \quad \quad s = \text{Vs} E - (\text{set} \text{cyc}); \\
& \quad \quad \text{quotG} = \text{quot.quotG} (\text{quot_fun} s u) u; \\
& \quad \quad \text{refine} = \text{quot.refine} (\text{quot_fun} s u) u \text{cyc} E M \\
& \quad \quad \text{in} (\text{case} \text{find_aug_path} (\text{quotG} E) (\text{quotG} M) \text{ of Some} p' \Rightarrow \text{Some} (\text{refine} p') \\
& \quad \quad \quad | \_ \Rightarrow \text{None}) \\
& \quad | \_ \Rightarrow \text{None})
\end{align*}
\]

\text{lemma} \text{find_aug_path_sound:}
\text{assumes}
\text{matching} M \text{ and } M \subseteq E \text{ and } \text{finite} M
\text{and}
\forall e \in E. \exists u, v. e = \{u, v\} \land u \neq v \text{ and } \text{finite} (\text{Vs} E)
\text{and}
\text{find_aug_path} E M = \text{Some} p
\text{shows} \text{augmenting_path} M p \land \text{path} E p \land \text{distinct} p

\text{lemma} \text{find_aug_path_complete:}
\text{assumes}
\text{augmenting_path} M p \text{ and } \text{path} E p \land \text{distinct} p
\text{and}
\text{matching} M \text{ and } M \subseteq E \text{ and } \text{finite} M
\text{and}
\forall e \in E. \exists u, v. e = \{u, v\} \land u \neq v \text{ and } \text{finite} (\text{Vs} E)"
\text{shows} \exists p'. \text{find_aug_path} E M = \text{Some} p'

Note that in \text{find_aug_path}, we instantiate both arguments \text{P} \text{ an} \text{a} of the locale \text{quot} to obtain the quotienting function \text{quotG} and the function for refining augmenting path \text{refine}.

Lastly, what follows shows the validity of instantiating the functional argument of \text{find_max_matching} with \text{find_aug_path}, which gives us the following soundness theorem of the resulting algorithm.

\text{lemma} \text{find_max_matching_works:}
\text{assumes}
\text{finite} (\text{Vs} E) \text{ and } \forall e \in E. \exists u, v. e = \{u, v\} \land u \neq v
\text{shows}
\text{find_max_match.find_max_matching} \text{find_aug_path} E \{\} \subseteq E
\text{matching} (\text{find_max_match.find_max_matching} \text{find_aug_path} E \{\})
\text{finite} (\text{find_max_match.find_max_matching} \text{find_aug_path} E \{\})
\forall M. \text{matching} M \land M \subseteq E \land \text{finite} M
\implies \text{card} M \leq \text{card} (\text{find_max_match.find_max_matching} \text{find_aug_path} E \{\})
5.5 Computing Blossoms and Augmenting Paths

Until now, we have only assumed the existence of the function \texttt{Compute_Blossom}, which can compute augmenting paths or blossoms, if any exist in the graph. We now refine that to an algorithm which, given two alternating paths resulting from the ascent of alternating trees, returns either an augmenting path or a blossom.

We first introduce some notions and notation. For a list \( l \) and a natural number \( n \), let \(\text{drop} \ n \ l\) denote the list \( l \) but with the first \( n \) elements dropped. For a list \( l \), let \( h :: l \) denote adding an element \( h \) to the front of a list \( l \). For a non-empty list \( l \), let \(\text{first} \ l\) and \(\text{last} \ l\) denote the first and last elements of \( l \), respectively. Also, for a list \( l \), let \(\text{rev} \ l\) denote its reverse. For two lists \( l_1 \) and \( l_2 \), let \( l_1 \sim l_2\) denote their concatenation. Also, let \(\text{longest_disj_pref} l_1 l_2\) denote the pair of lists \(\langle l_1', l_2' \rangle\), where \(l_1'\) and \(l_2'\) are the longest disjoint prefixes of \( l_1 \) and \( l_2 \), respectively, s.t. \( \text{last} l_1' = \text{last} l_2' \). Note: \(\text{longest_disj_pref} l_1 l_2\) is only well-defined if there are \( l_1', l_2' \), and \( l \) s.t. \( l_1 = l_1' \sim l \) and \( l_2 = l_2' \sim l \), and if both \( l_1' \) and \( l_2' \) are disjoint except at their endpoints.

We now are able to state the following two lemmas concerning the construction of a blossom or an augmenting path given paths resulting from alternating trees search.

\hspace{1cm} ▷ Lemma 1. Assume the function \texttt{compute_alt_path}(\( G, M \)) returns two lists of vertices \( \langle \gamma_1, \gamma_2 \rangle\) s.t. first \( \gamma_1 \) and first \( \gamma_2 \) are both (i) simple paths w.r.t. \( G \), (ii) alternating paths w.r.t. \( M \), (iii) of odd length, and if we have that (iv) \( \text{last} \ \gamma_1 = \text{last} \ \gamma_2 \), (v) \( \text{last} \ \gamma_1 \not\in \bigcup M \), (vi) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in M \cup M, (vii) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in \bigcup M \), and (viii) \(\text{longest_disj_pref} \ \gamma_1 \ \gamma_2\) is well-defined and \(\langle \gamma_1', \gamma_2' \rangle = \text{longest_disj_pref} \ \gamma_1 \ \gamma_2\), then \(\text{rev} (\text{drop} (\langle |\gamma_1'| - 1 \rangle \ \gamma_1), \text{rev} \ \gamma_1') \sim \gamma_2'\) is a blossom w.r.t. \( G, M \).

\hspace{1cm} ▷ Lemma 2. If \( \gamma_1 \) and \( \gamma_2 \) are both (i) simple paths w.r.t. \( G \), (ii) alternating paths w.r.t. \( M \), (iii) of odd length, and (iv) disjoint, and if we have that (v) \( \text{last} \ \gamma_1 \not\in \bigcup M \), (vi) \( \text{last} \ \gamma_2 \not\in \bigcup M \), (vii) \( \text{last} \ \gamma_1 \not\in \text{last} \ \gamma_2 \), and (viii) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in M \cup M, (ix) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in \bigcup M \), then \(\text{rev} \ \gamma_1' \sim \gamma_2\) is an augmenting path w.r.t. \( G, M \).

Based on the above lemmas we refine the algorithm \texttt{Compute_Blossom} as shown in Algorithm 3.

\hspace{1cm} Algorithm 3: \texttt{Compute_Blossom}(\( G, M \))

\begin{verbatim}
if \exists e \in G.e \cap \bigcup M = \emptyset
  return Augmenting path choose \{ e | e \in G \land e \cap \bigcup M = \emptyset \}
else if compute_alt_path(\( G, M \)) = (\( \gamma_1, \gamma_2 \))
  if last \( \gamma_1 \not\neq \text{last} \ \gamma_2
    return Augmenting path (\text{rev} \ \gamma_1') \sim \gamma_2
  else
    (\( \gamma_1', \gamma_2' \)) = \text{longest_disj_pref} \ \gamma_1 \ \gamma_2
    return Blossom (\text{rev} (\text{drop} (\langle |\gamma_1'| - 1 \rangle \ \gamma_1), \text{rev} \ \gamma_1') \sim \gamma_2')
else
  return No blossom or augmenting path found
\end{verbatim}

The following corollary shows the conditions under which \texttt{Compute_Blossom} works.

\hspace{1cm} ▷ Corollary 3. Assume the function \texttt{compute_alt_path}(\( G, M \)) returns two lists of vertices \( \langle \gamma_1, \gamma_2 \rangle\) s.t. both lists are (i) simple paths w.r.t. \( G \), (ii) alternating paths w.r.t. \( M \), and (iii) of odd length, and also (iv) \( \text{last} \ \gamma_1 \not\in \bigcup M \), (v) \( \text{last} \ \gamma_2 \not\in \bigcup M \), (vi) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in G \cup M \), and (vii) \{first \( \gamma_1\), first \( \gamma_2\)\} \not\in \bigcup M \), iff two lists of vertices with those properties exist. Then there is
a blossom or an augmenting path w.r.t. $(\mathcal{G}, M)$ iff $\text{Compute\_Blossom}(\mathcal{G}, M)$ is a blossom or an augmenting path w.r.t. $(\mathcal{G}, M)$.

In Isabelle/HOL, to formalise the function $\text{Compute\_Blossom}$, we firstly defined a function, $\text{longest\_disj\_pfx}$, which finds the longest common prefix in a straightforward fashion with a quadratic worst-case runtime. The formalised versions of Lemma 1 and 2, which show that the output of $\text{longest\_disj\_pfx}$ can be used to construct a blossom or an augmenting path are as follows:

**lemma common_pfxs_form_blossom:**

assumes

$(\text{Some } pfx1, \text{Some } pfx2) = \text{longest\_disj\_pfx} \ p1 \ p2$\p2
and

$p1 = pfx1 \ @ \ p$ and $p2 = pfx2 \ @ \ p$
and

$\text{alt\_path} \ M \ p1$ and $\text{alt\_path} \ M \ p2$ and $\text{last} \ p1 \notin \text{Vs} \ M$ and $\{\text{hd} \ p1, \text{hd} \ p2\} \in M$
and

$\text{hd} \ p1 \neq \text{hd} \ p2$
and

$\text{even} \ (\text{length} \ p1)$ and $\text{even} \ (\text{length} \ p2)$
and

$\text{distinct} \ p1$ and $\text{distinct} \ p2$
and

$\text{matching} \ M$

shows $\text{blossom} \ M \ (\text{rev} \ (\text{drop} \ (\text{length} \ pfx1) \ p1)) \ (\text{rev} \ pfx1 \ @ \ pfx2)$

**lemma construct_aug_path:**

assumes

$\text{set} \ p1 \cap \text{set} \ p2 = \emptyset$
and

$p1 \neq []$ and $p2 \neq []$
and

$\text{alt\_path} \ M \ p1$ and $\text{alt\_path} \ M \ p2$ and $\text{last} \ p1 \notin \text{Vs} \ M$ and $\text{last} \ p2 \notin \text{Vs} \ M$
and

$\{\text{hd} \ p1, \text{hd} \ p2\} \in M$
and

$\text{even} \ (\text{length} \ p1)$ and $\text{even} \ (\text{length} \ p2)$

shows $\text{augmenting\_path} \ M \ ((\text{rev} \ p1) \ @ \ p2)$

The function $\text{Compute\_Blossom}$ is formalised as follows:

```
"compute\_blossom \ G \ M \equiv
(if \ (\exists \ e. \ e \in \text{unmatched\_edges} \ G \ M) \ then
  let
    singleton\_path =
      (SOME \ p. \exists \ v1 \ v2. \ p = [v1 ,v2] \wedge \{v1, v2\} \in \text{unmatched\_edges} \ G \ M)
    in
      Some \ (\text{Path} \ \text{singleton\_path})
  else
    case \ compute\_alt\_path \ G \ M
      of \ Some \ (p1,p2) \Rightarrow
        (if \ (\text{set} \ p1 \cap \text{set} \ p2 = \emptyset) \ then
          Some \ (\text{Path} \ ((\text{rev} \ p1) \ @ \ p2))
        else
          (let
```

```
\[(pfx_1, pfx_2) = \text{longest_disj_pfx} \ p1 \ p2;\]
\[\text{stem} = (\text{rev} \ (\text{drop} \ (\text{length} \ (\text{the} \ pfx_1)) \ p1));\]
\[\text{cycle} = (\text{rev} \ (\text{the} \ pfx_1) @ (\text{the} \ pfx_2))\]
\[
\begin{array}{c}
\text{in}
\end{array}
\]
\[
(\text{Some} \ (\text{Blossom} \ \text{stem} \ \text{cycle})))
\]
\[
\ |
\]
\[
\Rightarrow \ None
\]

We use a locale again to formalise that function. That locale parameterises it on a function that searches for alternating paths and poses the soundness and completeness assumptions for that alternating path search function. This function is equivalent to the unspecified function \text{compute_alt_path} in Corollary 3 and locale’s assumptions on it are formalised statements of the seven assumptions on \text{compute_alt_path} in Corollary 3.

### 5.6 Computing Alternating Paths

Lastly, we refine the function \text{compute_alt_path} to an algorithmic specification. The algorithmic specification of that function performs the alternating tree search, see Algorithm 4. If the function positively terminates, i.e. finding two vertices with even labels, returns two alternating paths by ascending the two alternating trees to which the two vertices belong. This tree ascent is performed by the function \text{follow}. That function takes a functional argument \(f\) and a vertex, and returns the singleton list \([u]\) if \(f(u) = \text{None}\), and \(u :: (\text{follow} \ f \ (f(u)))\) otherwise.

```plaintext
Algorithm 4: compute_alt_path(G, M)

ex = ∅ // Set of examined edges
foreach u ∈ ∪G
  label u = None
  parent u = None
U = ∪G \ ∪M // Set of unmatched vertices
foreach u ∈ U
  label u = ⟨u, even⟩
while (G \ ex) ∩ \{e | ∃u ∈ e, r ∈ ∪G. label u = ⟨r, even⟩\} ≠ ∅
  // Choose a new edge and labelled it examined
  \{u_1, u_2\} = choose (G \ ex) ∩ \{u_1, u_2 \ | \exists r. \text{label} u_1 = ⟨r, even⟩\}
  ex = ex ∪ {\{u_1, u_2\}}
  if label u_2 = None
    // Grow the discovered set of edges from r by two
    u_3 = choose \{u_3 \ | \{u_2, u_3\} ∈ M\}
    ex = ex ∪ \{\{u_2, u_3\}\}
    label u_2 = ⟨r, odd⟩; \text{label} u_3 = ⟨r, even⟩; parent u_2 = u_1; parent u_3 = u_2
  else if ∃s ∈ ∪G. label u_2 = ⟨s, even⟩
    // Return two paths from current edge’s tips to unmatched vertex(es)
    return (follow parent u_1, follow parent u_2)
return No paths found
```

The soundness and completeness of Algorithm 4 is stated as follows.

\begin{itemize}
  \item \textbf{Theorem 3.} The function \text{compute_alt_path}(G, M) returns two lists of vertices \(⟨γ_1, γ_2⟩\) s.t. both lists are (i) simple paths w.r.t. \(G\), (ii) alternating paths w.r.t. \(M\), and (iii) of
odd length, and also (iv) last $γ_1 \not\in \bigcup \mathcal{M}$, (v) last $γ_2 \not\in \bigcup \mathcal{M}$, (vi) \{first $γ_1$, first $γ_2$\} $\not\in \mathcal{G}$, and (vii) \{first $γ_1$, first $γ_2$\} $\not\in \mathcal{M}$, if two lists of vertices with those properties exist.

The primary difficulty with proving this theorem is identifying the loop invariants, which are as follows:

(i) For any vertex $u$, if for some $r$, label $u = \langle r, \text{even} \rangle$, then the vertices in the list follow parent $u$ have labels that alternate between $\langle r, \text{even} \rangle$ and even $\langle r, \text{odd} \rangle$.
(ii) For any vertex $u_1$, if for some $r$ and some $l$, we have label $u_1 = \langle r, l \rangle$, then the list follow parent $u_1$, made of the vertices list $u_1u_2 \ldots u_n$, has the following property: if label $u_i = \langle r, \text{even} \rangle$ and label $u_{i+1} = \langle r, \text{odd} \rangle$, for some $r$, then $\{u_1, u_{i+1}\} \in \mathcal{M}$, otherwise, $\{u_i, u_{i+1}\} \not\in \mathcal{M}$.

(iii) The relation induced by the function parent is well-founded.
(iv) For any $\{u_1, u_2\} \in \mathcal{M}$, label $u_1 = \text{None}$ iff label $u_2 = \text{None}$.
(v) For any $u_1$, if label $u_1 = \text{None}$ then parent $u_2 \not= u_1$, for all $u_2$.
(vi) For any $u$, if label $u \not= \text{None}$, then last (follow parent $u$) $\not\in \bigcup \mathcal{M}$.
(vii) For any $u$, if label $u \not= \text{None}$, then label (last (follow parent $u$)) = $\langle r, \text{even} \rangle$, for some $r$.
(viii) For any $\{u_1, u_2\} \in \mathcal{M}$, if label $u_1 \not= \text{None}$, then $\{u_1, u_2\} \in \text{ex}$.
(ix) For any $u$, follow parent $u$ is a simple path w.r.t. $\mathcal{G}$.

(x) Suppose we have two vertex lists $γ_1$ and $γ_2$, s.t. both lists are (i) simple paths w.r.t. $\mathcal{G}$, (ii) alternating paths w.r.t. $\mathcal{M}$, and (iii) of odd length, and also (iv) last $γ_1 \not\in \bigcup \mathcal{M}$, (v) last $γ_2 \not\in \bigcup \mathcal{M}$, (vi) \{first $γ_1$, first $γ_2$\} $\in \mathcal{G}$, and (vii) \{first $γ_1$, first $γ_2$\} $\not\in \mathcal{M}$. Then there is at least an edge from the path rev $γ_1 \sim γ_2$ which is a member of neither $\mathcal{M}$ nor ex.\footnote{The hypothesis of this invariant is equivalent to the existence of an augmenting path or a blossom w.r.t. $\langle \mathcal{G}, \mathcal{M} \rangle$.}

To formalise Algorithm 4 in Isabelle/HOL, we first define the function which follows a vertex’s parent as follows:

\[
\text{follow } v = \text{case } (\text{parent } v) \text{ of } \text{Some } v' \Rightarrow v # (\text{follow } v') \mid _\_ \Rightarrow [v])
\]

Again, we use a locale to formalise that function, and that locale fixes the function parent. Note that the above function is not well-defined for all possible arguments. In particular, it is only well-defined if the relation between pairs of vertices induced by the function parent is a well-founded relation. This assumption on parent is a part of the locale’s definition.

Then, we then formalise compute_alt_path as follows:

\[
\text{compute_alt_path ex par flabel} =
\begin{align*}
\text{if } (\exists v_1. v_2. \{v_1, v_2\} \subseteq \mathcal{G} - \text{ex} \land (\exists r. \text{flabel } v_1 = \text{Some } (r, \text{Even}))) \text{ then let} \\
(v_1, v_2) = (\text{Some } (v_1, v_2)). \{v_1, v_2\} \subseteq \mathcal{G} - \text{ex} \land \\
(\exists r. \text{flabel } v_1 = \text{Some } (r, \text{Even})) \\
\text{ex}' = \text{insert } \{v_1, v_2\} \text{ ex}; \\
r = (\text{Some } r. \text{flabel } v_1 = \text{Some } (r, \text{Even})) \\
\text{in} \\
(\text{if } \text{flabel } v_2 = \text{None} \land (\exists v_3. \{v_2, v_3\} \subseteq \mathcal{M}) \text{ then let} \\
v_3 = (\text{Some } v_3. \{v_2, v_3\} \subseteq \mathcal{M}); \\
p_{r'} = \text{par}(v_2 := \text{Some } v_1, v_3 := \text{Some } v_2); \\
\text{flabel}' = \text{flabel}(v_2 := \text{Some } (r, \text{Odd}), v_3 := \text{Some } (r, \text{Even}));
\end{align*}
\]
\[ \text{ex'} = \text{insert } \{v2, v3\} \text{ ex'}; \]
\[ \text{return} = \text{compute_alt_path ex'} \text{ par' flabel'} \]
\[ \text{in} \]
\[ \text{return} \]
\[ \text{else if } \exists r. \text{ flabel v2} = \text{Some (r, Even)} \text{ then} \]
\[ \text{let} \]
\[ r' = (\text{SOME } r'. \text{ flabel v2} = \text{Some (r', Even)}); \]
\[ \text{return} = \text{Some (parent.follw par v1, parent.follw par v2)} \]
\[ \text{in} \]
\[ \text{return} \]
\[ \text{else} \]
\[ \text{let} \]
\[ \text{return} = \text{None} \]
\[ \text{in} \]
\[ \text{return} \]
\[ \text{else} \]
\[ \text{let} \]
\[ \text{return} = \text{None} \]
\[ \text{in} \]
\[ \text{return} \]

Note that we do not use a while combinator to represent the while loop: instead we formalise it recursively, passing the context along recursive calls. In particular, we define it as a recursive function which takes as arguments the variables representing the state of the while loop, namely, the set of examined edges \( \text{ex} \), the parent function \( \text{par} \), and the labelling function \( \text{flabel} \).

5.7 Discussion

The algorithm in LEDA differs from the description above in one aspect. If no augmenting path is found, an odd-set cover is constructed proving optimality. Also the correctness proof uses the odd-set cover instead of the fact that an augmenting path exists in the original graph if and only if one exists in the quotient graph.

For an efficient implementation, the shrinking process and the lifting of augmenting paths are essential. The shrinking process is implemented using a union-find data structure and the lifting is supported by storing additional information with the edge that closes the cycle in a blossom [35].

6 Level Five of Trustworthiness: Extraction of Efficient Executable Code

In this section we examine the process of obtaining trustworthy executable and efficient code from algorithms verified in theorem provers. First we discuss the problem in general and then we examine our formalization of the blossom-shrinking algorithm.

Most theorem provers are connected to a programming language of some sort. Frequently, as in the case of Isabelle/HOL, that programming language is a subset of the logic and close to a functional programming language. The theorem prover will usually support the extraction of actual code in some programming language. Isabelle/HOL supports Standard ML, Haskell, OCaml and Scala.

To show that code extraction “works”, here are some random non-trivial examples of verifications that have resulted in reasonably efficient code: Compilers for C [30] and for

We will now discuss some approaches to obtaining code from function definitions in a theorem prover. In the ACL2 theorem prover all functions are defined in a purely functional subset of Lisp and are thus directly executable. In other systems, code generation involves an explicit translation step. The trustworthiness of this step varies. Probably the most trustworthy code generator is that of HOL4, because its backend is a verified compiler for CakeML [24], a dialect of ML. The step from HOL to CakeML is not verified once and for all, but every time it is run it produces a theorem that can be examined and that states the correctness of this run [37]. The standard code generator in Isabelle/HOL is unverified (although its underlying theory has been proved correct on paper [19]). There is ongoing work to replace it with a verified code generator that produces CakeML [20].

So far we have only considered purely functional code but efficient algorithms often make use of imperative features. Some theorem provers support imperative languages directly, e.g. Java [4]. We will now discuss how to generate imperative code from purely functional ones. Clearly the code generator must turn the purely functional definitions into more imperative ones. The standard approach [7, 37] is to let the code generator recognize monadic definitions (a purely functional way to express imperative computations) and implement those imperatively. This is possible because many functional programming languages do in fact offer imperative features as well.

Just as important as the support for code extraction is the support for verified stepwise refinement of data types and algorithms by the user. Data refinement means the replacement of abstract data types by concrete efficient ones, e.g. sets by search trees. Algorithm refinement means the stepwise replacement of abstract high-level definitions that may not even be executable by efficient implementations. Both forms of refinement are supported well in Isabelle/HOL [17, 25, 26].

We conclude this section with a look at code generation from our formalization of the blossom-shrinking algorithm. It turns out that our formalization is almost executable as is. The only non-executable construct we used is \texttt{SOME x. P} that denotes some arbitrary \( x \) that satisfies the predicate \( P \). Of course one can hide arbitrarily complicated computations in such a construct but we have used it only for simple nondeterministic choices and it will be easy to replace. For example, one can obtain an executable version of function \texttt{choose_con_vert} (see Section 5.4) by defining a function that searches the vertex list \( vs \) for the first \( v' \) such that \( \{v, v'\} \in E \). This is an example of algorithm refinement. To arrive at efficient code for the blossom-shrinking algorithm as a whole we will need to apply both data and algorithm refinement down to the imperative level. At least the efficient implementations referred to above, just before Section 5.1, are intrinsically imperative.

Finally let us note that instead of code generation it is also possible to verify existing code in a theorem prover. This was briefly mentioned in Section 4 and Charguéraud [8] has followed this approach quite successfully.

\section{The Future}

The state of the art in the verification of complex algorithms has improved enormously over the last decade. Yet there is still a lot to do on the path to a verified library such as LEDA. Apart from the sheer amount of material that would have to be verified there is the challenge of obtaining trustworthy code that is of comparable efficiency. This requires trustworthy code generation for a language such C or C++, including the memory management. This is
a non-trivial task, but some of the pieces of the puzzle, like a verified compiler, are in place already.
